Programming

Aykut Erdem // Koç University // Fall 2020

Recap

- Shared Libraries
- Case study: Library interpositioning
- The heap so far
- What is a heap allocator?
- Heap allocator requirements and goals
- Method 0: Bump Allocator

Plan for Today

- Method 1: Implicit Free List Allocator
- Method 2: Explicit Free List Allocator

Disclaimer: Slides for this lecture were borrowed from

—Nick Troccoli's Stanford CS107 class

Recap: Heap Allocator Requirements

A heap allocator must...

- 1. Handle arbitrary request sequences of allocations and frees
- 2. Keep track of which memory is allocated and which is available
- 3. Decide which memory to provide to fulfill an allocation request
- 4. Immediately respond to requests without delay
- 5. Return addresses that are 8-byte-aligned (must be multiples of 8).

Recap: Heap Allocator Goals

- Goal 1: Maximize **throughput**, or the number of requests completed per unit time. This means minimizing the average time to satisfy a request.
- <u>Goal 2:</u> Maximize memory **utilization**, or how efficiently we make use of the limited heap memory to satisfy requests.

Recap: Bump Allocator

- A **bump allocator** is a heap allocator design that simply allocates the next available memory address upon an allocate request and does nothing on a free request.
- Throughput: each malloc and free execute only a handful of instructions:
 - It is easy to find the next location to use
 - Free does nothing!
- Utilization: we use each memory block at most once. No freeing at all, so no memory is ever reused. 🕾

Recap: Bump Allocator

- A bump allocator is an extreme heap allocator it optimizes only for throughput, not utilization.
- Better allocators strike a more reasonable balance. How can we do this?

Questions to consider:

- 1. How do we keep track of free blocks?
- 2. How do we choose an appropriate free block in which to place a newly allocated block?
- 3. After we place a newly allocated block in some free block, what do we do with the remainder of the free block?
- 4. What do we do with a block that has just been freed?

Lecture Plan

- Method 1: Implicit Free List Allocator
- Method 2: Explicit Free List Allocator

- **Key idea:** in order to reuse blocks, we need a way to track which blocks are allocated and which are free.
- We could store this information in a separate global data structure, but this is inefficient.
- Instead: let's allocate extra space before each block for a **header** storing its payload size and whether it is allocated or free.
- When we allocate a block, we look through the blocks to find a free one, and we update its header to reflect its allocated size and that it is now allocated.
- When we free a block, we update its header to reflect it is now free.
- The header should be 8 bytes (or larger).
- By storing the block size of each block, we implicitly have a list of free blocks.

```
void *a = malloc(4);
void *b = malloc(8);
void *c = malloc(4);
free(b);
void *d = malloc(8);

Representing Headers

How can we store both a size and a status (Free/Allocated) in 8 bytes?

Int for size, int for status? no! malloc/realloc use size_t for sizes!

Key idea: block sizes will *always be multiples of 8*. (Why?)

- Least-significant 3 bits will be unused!
- Solution: use one of the 3 least-significant bits to store free/allocated status

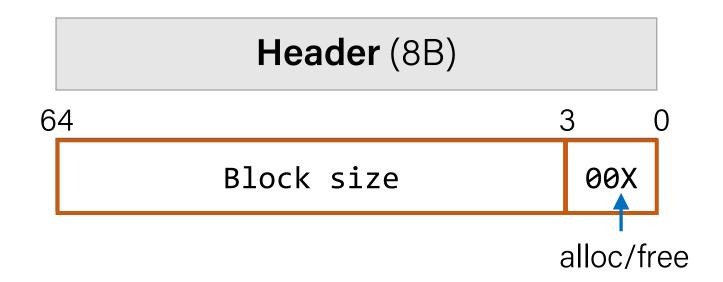

How can we choose a free block to use for an allocation request?

- First fit: search the list from beginning each time and choose first free block that fits.
- Next fit: instead of starting at the beginning, continue where previous search left off.
- Best fit: examine every free block and choose the one with the smallest size that fits.
- First fit/next fit easier to implement
- What are the pros/cons of each approach?

Implicit Free List Summary

For all blocks,

- Have a header that stores size and status.
- Our list links all blocks, allocated (A) and free (F).

Keeping track of free blocks:

- Improves memory utilization (vs bump allocator)
- Decreases throughput (worst case allocation request has O(A + F) time)
- Increases design complexity ©

Up to you!

```
void *e = malloc(16);
```

So far, we have seen that a reasonable allocation request splits a free block into an allocated block and a free block with remaining space. What about edge cases?

8 Free	a + pad	8 Used	d	8 Used	c + pad	16 Used		е	0 Free

Revisiting Our Goals

Questions we considered:

- 1. How do we keep track of free blocks? Using headers!
- 2. How do we choose an appropriate free block in which to place a newly allocated block? **Iterate through all blocks**.
- 3. After we place a newly allocated block in some free block, what do we do with the remainder of the free block? **Try to make the most of it!**
- 4. What do we do with a block that has just been freed? **Update its** header!

Coalescing

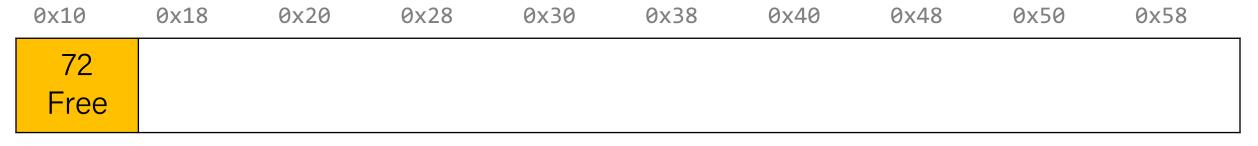

```
void *e = malloc(24); // returns NULL!
```

You do not need to worry about this problem for the implicit allocator, but this is a requirement for the *explicit* allocator! (More about this later).

0x10	0x18	0x20	0x28	0x30	0x38	0x40	0x48	0x50	0x58
8 Free		8 Free		8 Free		24 Used			

In-Place Realloc

```
void *a = malloc(4);
void *b = realloc(a, 8);
```

In-Place Realloc

```
void *a = malloc(4);
void *b = realloc(a, 8);
```

Variable	Value
a	0x10

0x10	0x18	0x20	0x28	0x30	0x38	0x40	0x48	0x50	0x58
8	a +	56							
Used	pad	Free							

In-Place Realloc

```
void *a = malloc(4);
void *b = realloc(a, 8);
```

Variable	Value
а	0x10
b	0x28

The implicit allocator can always move memory to a new location for a realloc request. The *explicit* allocator must support in-place realloc (more on this later).

0x10	0x18	0x20	0x28	0x30	0x38	0x40	0x48	0x50	0x58
8 Free	a + pad	8 Used	b	40 Free					

Summary: Implicit Allocator

 An implicit allocator is a more efficient implementation that has reasonable throughput and utilization due to its recycling of blocks.

Can we do better?

- 1. Can we avoid searching all blocks for free blocks to reuse?
- 2. Can we merge adjacent free blocks to keep large spaces available?
- 3. Can we avoid always copying/moving data during realloc?

Lecture Plan

- Method 1: Implicit Free List Allocator
- Method 2: Explicit Free List Allocator

Lecture Plan

- Method 1: Implicit Free List Allocator
- Method 2: Explicit Free List Allocator
 - Explicit Allocator
 - Coalescing
 - In-place realloc

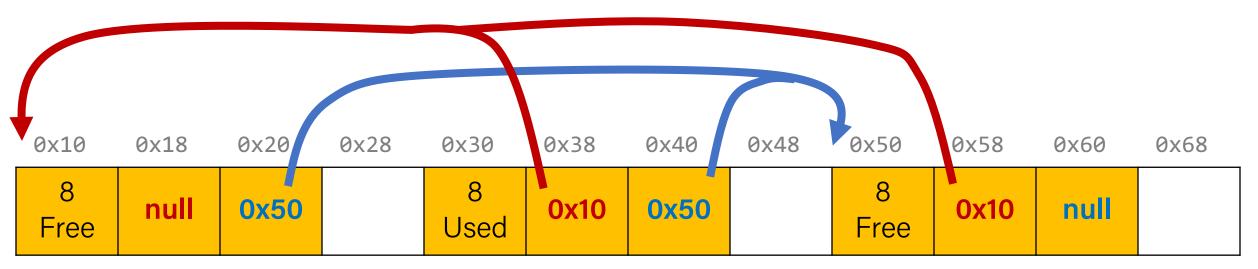

Can We Do Better?

- It would be nice if we could jump *just between free blocks*, rather than all blocks, to find a block to reuse.
- Idea: let's modify each header to add a pointer to the previous free block and a pointer to the next free block.

0x10 0x18	0x20	0x28	0x30	0x38	0x40	0x48	0x50	0x58	0x60	0x68

- **Idea:** let's modify each header to add a pointer to the previous free block and a pointer to the next free block.

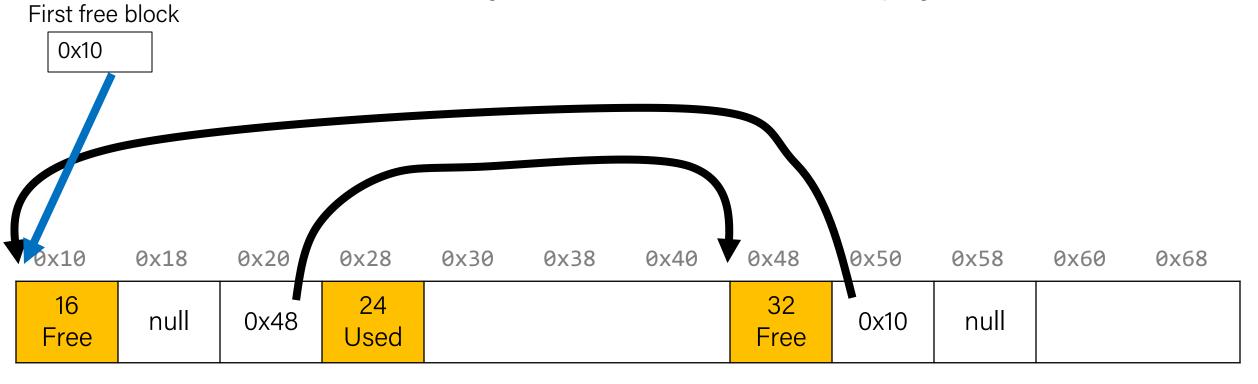

- It would be nice if we could jump *just between free blocks*, rather than all blocks, to find a block to reuse.
- **Idea:** let's modify each header to add a pointer to the previous free block and a pointer to the next free block. *This is inefficient / complicated.*
- Where can we put these pointers to the next/previous free block?
- Idea: In a separate data structure?

- It would be nice if we could jump *just between free blocks*, rather than all blocks, to find a block to reuse.
- Idea: let's modify each header to add a pointer to the previous free block and a pointer to the next free block. This is inefficient / complicated.
- Where can we put these pointers to the next/previous free block?
- Idea: In a separate data structure? More difficult to access in a separate place prefer storing near blocks on the heap itself.

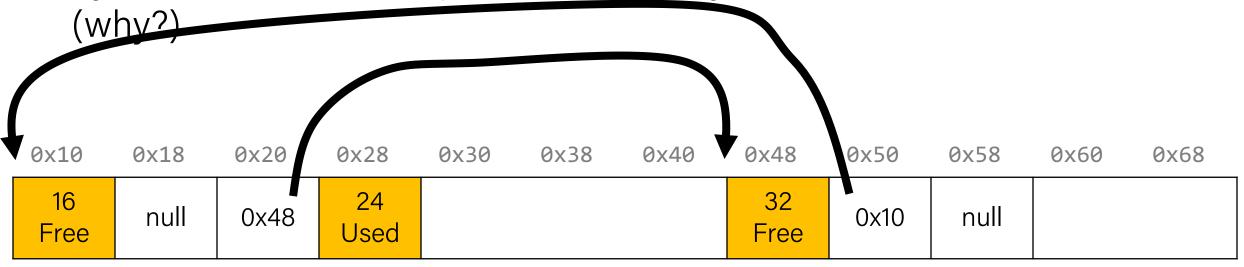

- Key Insight: the payloads of the free blocks aren't being used, because they're free.
- **Idea:** since we only need to store these pointers for free blocks, let's store them in the <u>first 16 bytes of each free block's payload!</u>

- **Key Insight:** the payloads of the free blocks aren't being used, because they're free.
- **Idea:** since we only need to store these pointers for free blocks, let's store them in the <u>first 16 bytes of each free block's payload!</u>

- **Key Insight:** the payloads of the free blocks aren't being used, because they're free.
- **Idea:** since we only need to store these pointers for free blocks, let's store them in the <u>first 16 bytes of each free block's payload!</u>
- This means each payload must be big enough to store 2 pointers (16 bytes). So we must require that for every block, free <u>and allocated.</u>

Explicit Free List Allocator

- This design builds on the implicit allocator, but also stores pointers to the next and previous free block inside each free block's payload.
- When we allocate a block, we look through just the free blocks using our linked list to find a free one, and we update its header and the linked list to reflect its allocated size and that it is now allocated.
- When we free a block, we update its header to reflect it is now free and update the linked list.

This **explicit** list of free blocks increases request throughput, with some costs (design and internal fragmentation)

Explicit Free List: List Design

How do you want to organize your explicit free list? (compare utilization/throughput)

- A. Address-order (each block's address is less than successor block's address)
- B. Last-in first-out (LIFO)/like a stack, where newly freed blocks are at the beginning of the list
- C. Other (e.g., by size, etc.)

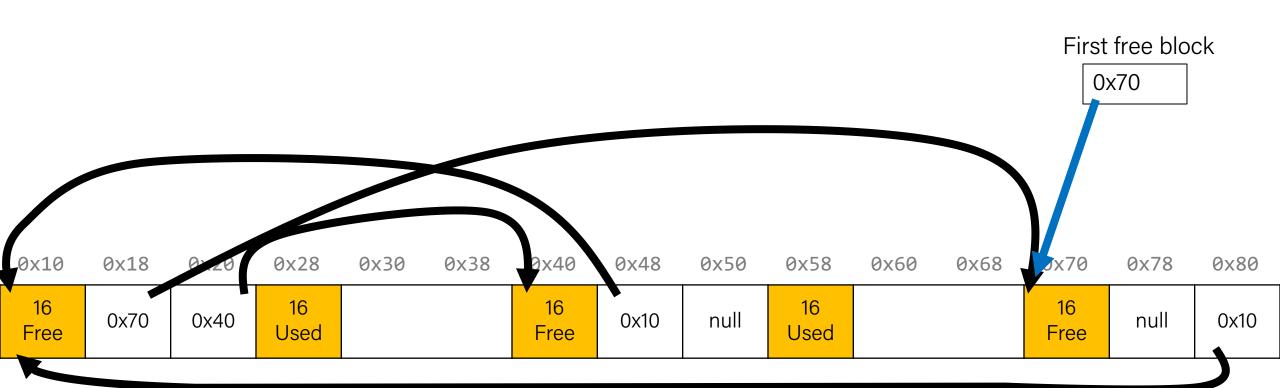

Up to you!

Better memory util, Linear free

Constant free (push recent block onto stack) st (more at end of lecture)

Explicit Free List: List Design

Note that the doubly-linked list does not have to be in address order.

Implicit vs. Explicit: So Far

Implicit Free List

 8B header for size + alloc/free status

- Allocation requests are worst-case linear in total number of blocks
- Implicitly address-order

Explicit Free List

- 8B header for size + alloc/free status
- Free block payloads store prev/next free block pointers
- Allocation requests are worst-case linear in number of free blocks
- Can choose block ordering

Revisiting Our Goals

Can we do better?

- Can we avoid searching all blocks for free blocks to reuse? Yes! We can use a doubly-linked list.
- 2. Can we merge adjacent free blocks to keep large spaces available?
- 3. Can we avoid always copying/moving data during realloc?

Revisiting Our Goals

                                                 0x40
                                                         0x48
                                                                 0x50
     40
                                                   16
                                                               C
    Free
                                                  Used
```

```
void *a = malloc(8);
void *b = malloc(8);
void *c = malloc(16);
free(b);
free(a);
void *d = malloc(32);
```

The process of combining adjacent free blocks is called coalescing.

For your explicit heap allocator, you should coalesce if possible when a block is freed. You only need to coalesce the most immediate right neighbor.

Revisiting Our Goals

Can we do better?

- 1. Can we avoid searching all blocks for free blocks to reuse? Yes! We can use a doubly-linked list.
- 2. Can we merge adjacent free blocks to keep large spaces available? Yes! We can coalesce on free().
- 3. Can we avoid always copying/moving data during realloc?

Revisiting Our Goals

Can we do better?

- Can we avoid searching all blocks for free blocks to reuse? Yes! We can use a doubly-linked list.
- 2. Can we merge adjacent free blocks to keep large spaces available? Yes! We can coalesce on free().
- 3. Can we avoid always copying/moving data during realloc?

Lecture Plan

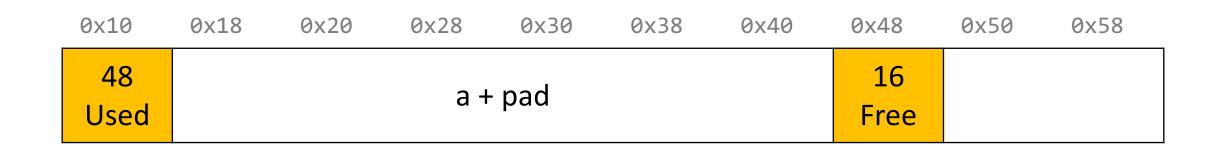

- Method 1: Implicit Free List Allocator
- Method 2: Explicit Free List Allocator
 - Explicit Allocator
 - Coalescing
 - In-place realloc

realloc

- For the implicit allocator, we didn't worry too much about realloc. We always moved data when they requested a different amount of space.
 - Note: realloc can grow or shrink the data size.
- But sometimes we may be able to keep the data in the same place.
 How?
 - Case 1: size is growing, but we added padding to the block and can use that
 - Case 2: size is shrinking, so we can use the existing block
 - Case 3: size is growing, and current block isn't big enough, but adjacent blocks are free.

```
void *a = malloc(42);
...
void *b = realloc(a, 48);
```

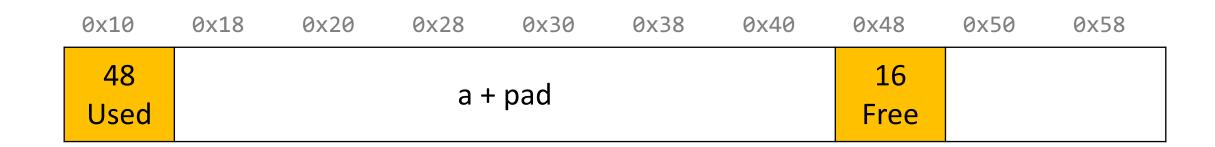

a's earlier request was too small, so we added padding. Now they are requesting a larger size we can satisfy with that padding! So realloc can return the same address.

```
void *a = malloc(42);
...
void *b = realloc(a, 16);
```

If a realloc is requesting to shrink, we can still use the same starting address.

If we can, we should try to recycle the now-freed memory into another freed block.

```
void *a = malloc(42);
...
void *b = realloc(a, 16);
```

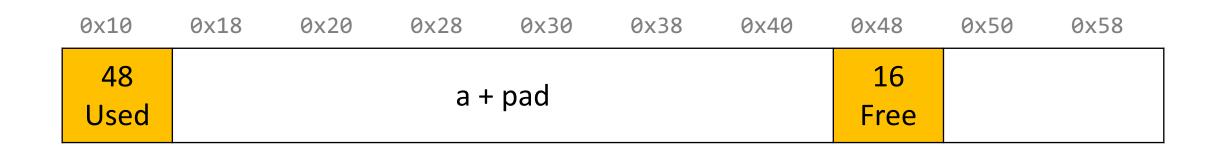

If a realloc is requesting to shrink, we can still use the same starting address.

If we can, we should try to recycle the now-freed memory into another freed block.

0x10	0x18	0x20	0x28	0x30	0x38	0x40	0x48	0x50	0x58
16 Used		а	24 Free		а		16 Free		

```
void *a = malloc(42);
...
void *b = realloc(a, 72);
```

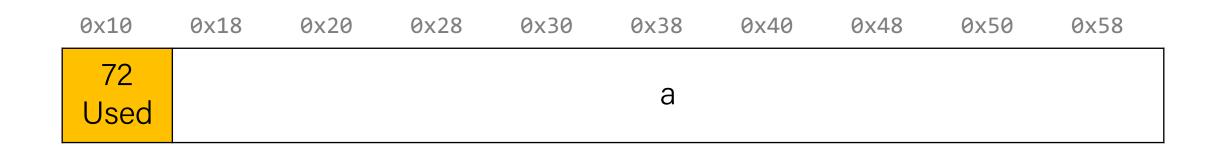

Even with the padding, we don't have enough space to satisfy the larger size. But we have an adjacent neighbor that is free – let's team up!

```
void *a = malloc(42);
...
void *b = realloc(a, 72);
```

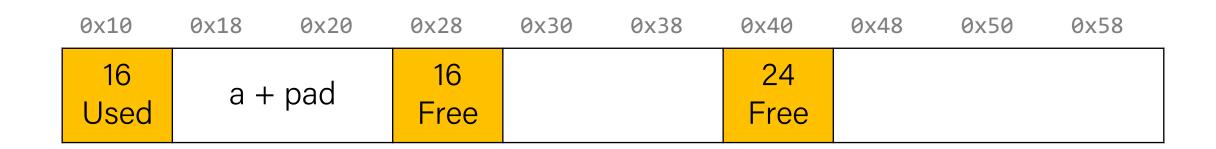

Even with the padding, we don't have enough space to satisfy the larger size. But we have an adjacent neighbor that is free – let's team up!

Now we can still return the same address.

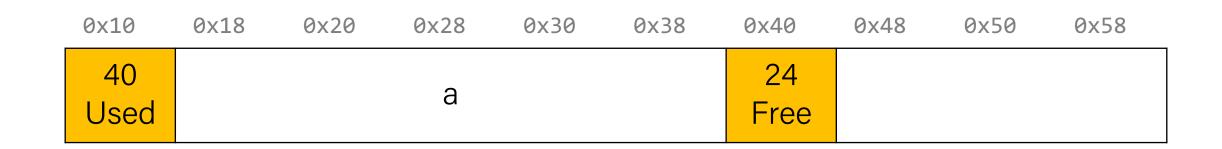

```
void *a = malloc(8);
...
void *b = realloc(a, 72);
```

For your project, you should combine with your *right* neighbors as much as possible until we get enough space, or until we know we cannot get enough space.

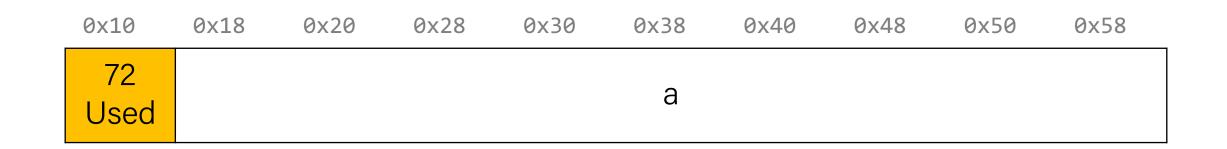

```
void *a = malloc(8);
...
void *b = realloc(a, 72);
```

For your project, you should combine with your *right* neighbors as much as possible until we get enough space, or until we know we cannot get enough space.

```
void *a = malloc(8);
...
void *b = realloc(a, 72);
```

For your project, you should combine with your right neighbors as much as possible until we get enough space, or until we know we cannot get enough space.

realloc

- For the implicit allocator, we didn't worry too much about realloc. We always moved data when they requested a different amount of space.
 - Note: realloc can grow or shrink the data size.
- But sometimes we may be able to keep the data in the same place.
 How?
 - Case 1: size is growing, but we added padding to the block and can use that
 - Case 2: size is shrinking, so we can use the existing block
 - Case 3: size is growing, and current block isn't big enough, but adjacent blocks are free.
- If you can't do an in-place realloc, then you should move the data elsewhere.

Practice 3

• For the following heap layout, what would the heap look like after the following request is made, assuming we are using an **explicit** free list allocator with a **first-fit** approach and **coalesce on free + realloc in-place**?

[24 byte payload, allocated for B] [16 byte payload, free] [16 byte payload, allocated for A]

free(B);

[48 byte payload, free] [16 byte payload, allocated for A]

Practice 4

 For the following heap layout, what would the heap look like after the following request is made, assuming we are using an explicit free list allocator with a first-fit approach and coalesce on free + realloc inplace?

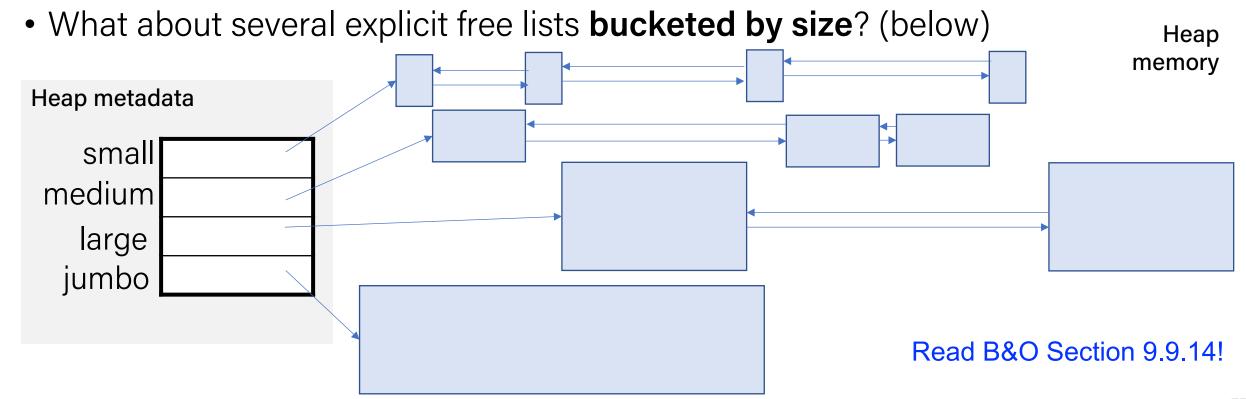

[16 byte payload, allocated for A] [32 byte payload, free] [16 byte payload, allocated for B]

realloc(A, 24);

[24 byte payload, allocated for A] [24 byte payload, free] [16 byte payload, allocated for B]

Going beyond: Explicit list w/size buckets

- Explicit lists are much faster than implicit lists.
- However, a first-fit placement policy is still linear in total # of free blocks.
- What about an explicit free list sorted by size (e.g., as a tree)?

Recap

- Method 1: Implicit Free List Allocator
- Method 2: Explicit Free List Allocator
