

Recap

- struct
- Generic stack

Plan for Today

- What really happens in GCC?
- Make and Makefiles

Disclaimer: Slides for this lecture were borrowed from

—Gabbi Fisher and Chris Chute's Stanford CS107 class

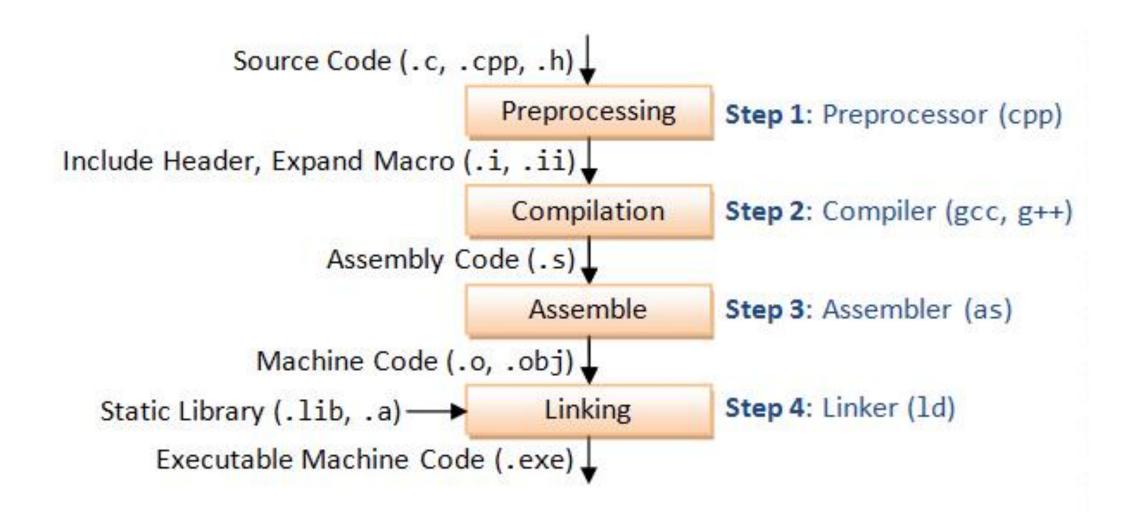

Lecture Plan

- What really happens in GCC?
 - -The Preprocessor
 - -The Compiler
 - -The Assembler
- Make and Makefiles

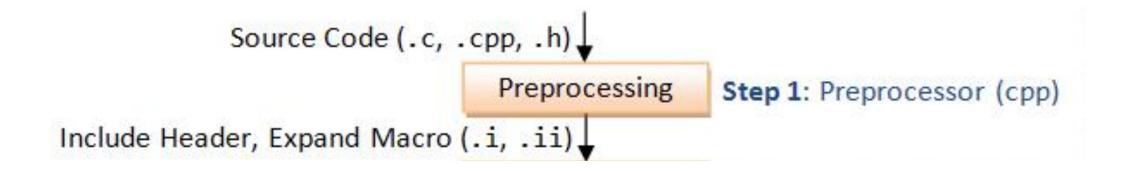

Compiling a C program with GCC

gcc -g -00 hello.c -o hello

The GNU Compiler Collection (GCC)

The GNU Compiler Collection (GCC)

The Preprocessor

#define

#include

The Preprocessor – Object Macros

```
#define BUFFER_SIZE 1024
foo = (char *) malloc (BUFFER_SIZE);
```

The Preprocessor - Object Macros

```
#define BUFFER_SIZE 1024
foo = (char *) malloc (BUFFER_SIZE);
=> foo = (char *) malloc (1024);
```

The Preprocessor – Function Macros

```
#define min(X, Y) ((X) < (Y) ? (X) : (Y))
y = min(1, 2);</pre>
```

The Preprocessor – Function Macros

```
#define min(X, Y) ((X) < (Y) ? (X) : (Y))
y = min(1, 2);
=> y = ((1) < (2) ? (1) : (2));</pre>
```

The Preprocessor – Imports

#include

The Preprocessor – Imports

```
header.h
char *test(void)
```

```
program.c
#include "header.h"
int x;
int main(int argc, char *argv[]) {
  puts(test());
```

The Preprocessor – Imports

```
header.h
char *test(void)
```

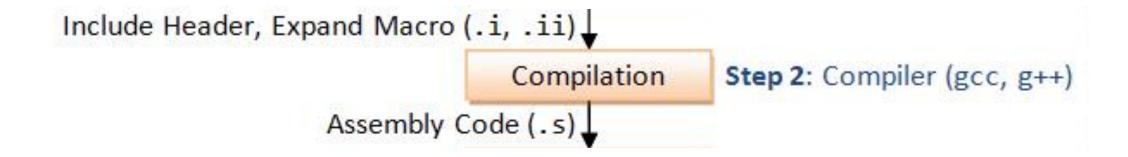

```
program.c
char *test(void);
int x;
int main(int argc, char *argv[]) {
  puts(test());
```

The Preprocessor – Demo

gcc -E -o hello.i hello.c

Preprocess hello.c, store output in hello.i

The GNU Compiler Collection (GCC)

The Compiler

• They're too complicated to explain in 5 minutes.

 It's important to know that they parse source code and compile it into assembly code. You will learn more about this in the second part the course.

The Compiler - Demo

gcc -S hello.i

Compile preprocessed i code into assembly instructions

The GNU Compiler Collection (GCC)

The Assembler – Demo

as -o hello.o hello.s

Assemble object code from hello.s

ELF: the Executable and Linkable Format

ELF: the Executable and Linkable Format

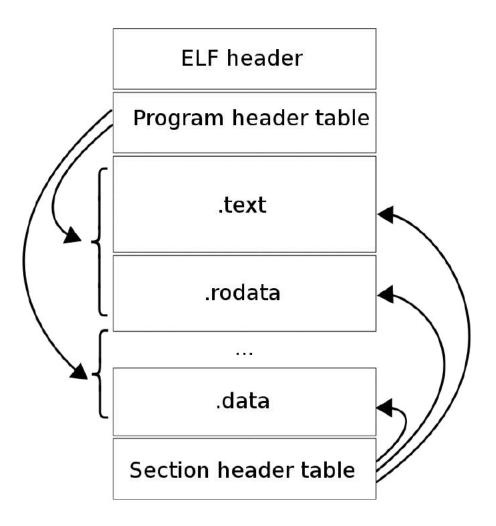

Cross-platform, used across multiple operating systems to represent components (object code) of a program. This comes in handy for linking and execution across different computers.

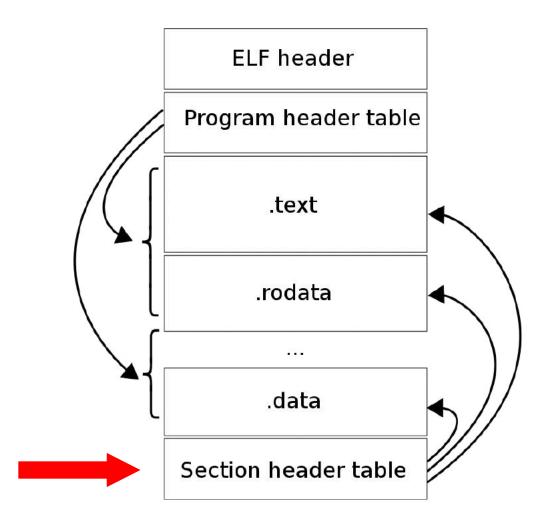

ELF: the Executable and Linkable Format

readelf -e hello.o

Actually read hello.o! "-e" flag is for printing headers out only

Section	Contents	Code Example
.text	Executable code (x86 assembly)	mov -0x8(%rbp),%rax
.data	Any global or static vars that have a predefined value and can be modified	int val = 3 (as global var)
.rodata	Variables that are only read (never written)	const int a = 0;
.bss	All uninitialized data; global variables and static variables initialized to zero or or not explicitly static int i; initialized in source code	static int i;
.comment	Comments about the generated ELF (details such as compiler version and execution platform)	

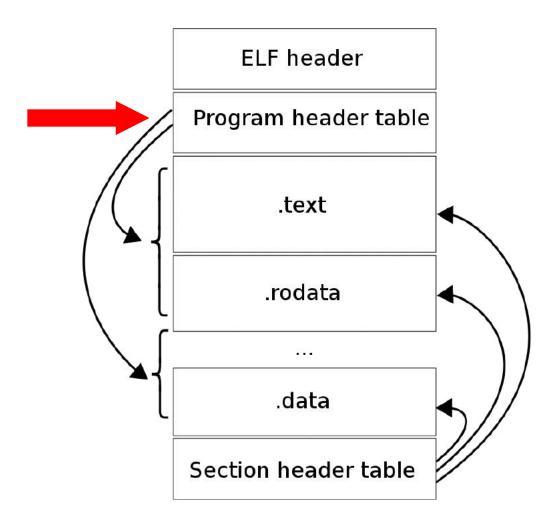

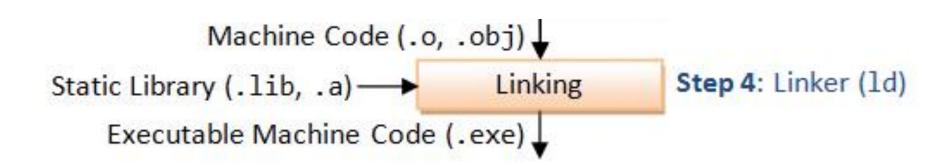

The Assembler

nm hello.o

Dump the variables and functions in hello and see what sections they belong to!

The GNU Compiler Collection (GCC)

The Linker - Shared vs. Static Libraries

Static Linking

- 1. When your program uses static linking, the machine code of external functions used in your program is copied into the executable.
- 2. A static library has file extension of ".a" (archive file) in Unix.

Dynamic Linking

- 1. When your program is dynamically linked, only an offset table is created in the executable. The operating system loads the machine code needed for external functions during execution—a process known as dynamic linking.
- 2. A shared library has file extension of ".so" (shared objects) in Unix.

The Linker

```
ld --dynamic-linker /lib64/ld-linux-x86-64.so.2 hello.o
  -o hello -lc --entry main
```

- 1. --dynamic-linker is used to specify the linker we must use to load stdlib.
- 2. -1c tells the linker to link to the standard C library.
- 3. --entry main specifies the entry point of the program (the method "main").

Note: You may not get this command working, because it will be slightly different on different Linux distributions

Finally...

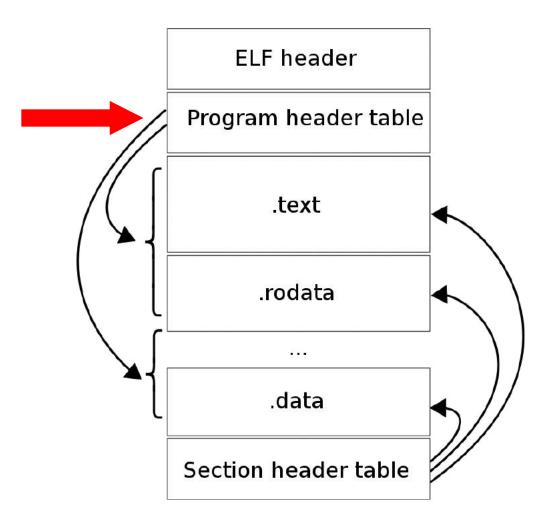

./hello

(Run your executable!)

The Executable

nm hello

Let's prove to ourselves linking did something...

Finally... (Really!)

./hello

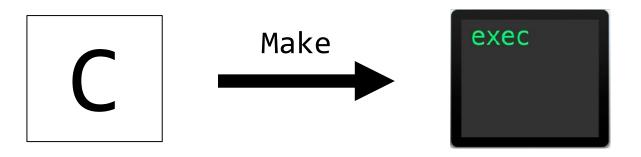

(Run your executable!)

Lecture Plan

- What really happens in GCC?
- Make and Makefiles
 - Overview of Make
 - Makefiles from scratch
 - Template for your Makefiles

Main Idea

- You write the "recipe"
- Make builds target

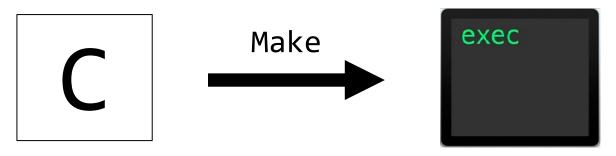

Main Idea

- You write the "recipe"
- Make builds target

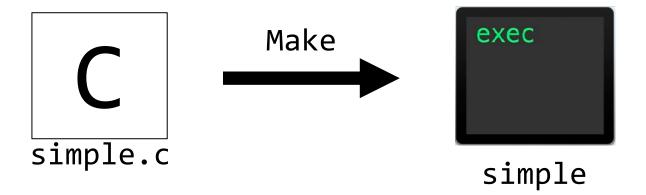

Definition

- "GNU Make is a tool which controls the generation of executables... from the program's source files."
- - GNU Make Docs

Example

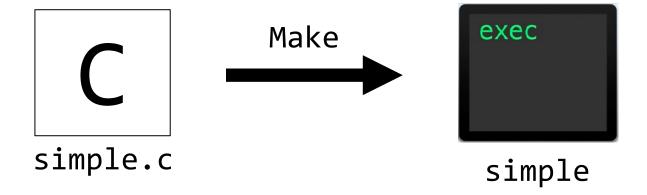

- Target: simple
- Ingredients: simple.c
- Recipe: gcc -o simple simple.c

Example

- Target: simple
- Ingredients: simple.c
- Recipe: gcc -o simple simple.c

Makefile Demo

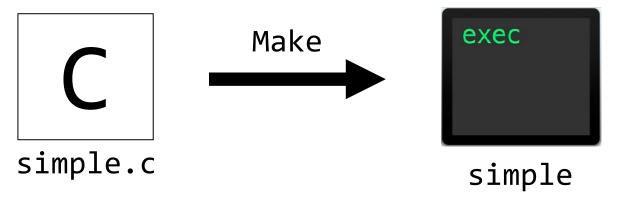

Example

- Target: simple
- Ingredients: simple.c
- Recipe: gcc -o simple simple.c

Makefile Demo

```
simple: simple.c
  gcc -o simple simple.c
```

No!

- More general
- Any target, any shell command

No!

- More general
- Any target, any shell command

Makefile Demo

No!

- More general
- Any target, any shell command

Makefile Demo

```
clean:
    rm -rf simple
```

Usage:

make clean

Advantages of Make

- General: Not just for compiling C source files
- Fast: Only rebuilds what's necessary
- Shareable: End users just call "make"

Makefiles

Makefile

- Makefile: A list of rules.
- Rule: Tells Make the commands to build a target from 0 or more dependencies

```
target: dependencies...
commands
```

•••

Makefiles

Makefile

- Makefile: A list of rules.
- Rule: Tells Make the commands to build a target from 0 or more dependencies

```
target: dependencies...

commands
...

Must indent with '\t', not spaces
```

Makefiles

Makefile = List of Rules

Rule: Tells Make how to get to a target from source files

```
target: dependencies...
commands
```

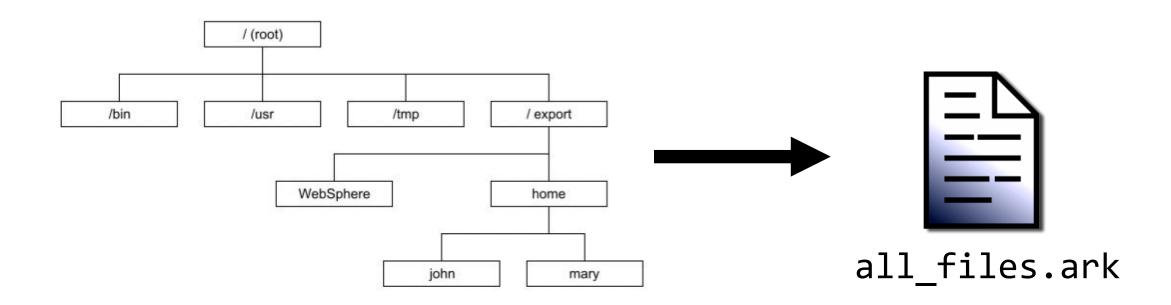

•••

"If dependencies have changed or don't exist, rebuild them...

Then execute these commands."

Realistic Example

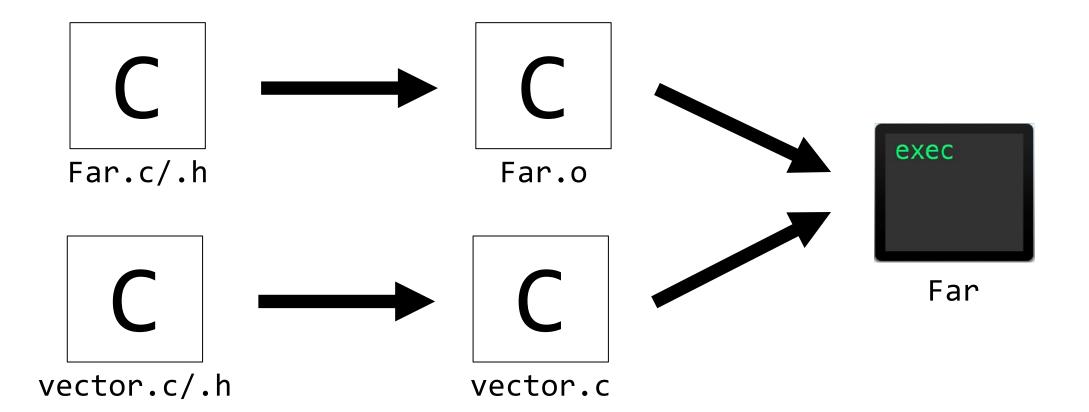

- Like Zip
- Traverses FS tree, builds a list of files
- Don't know length ahead of time? Need growable data structure

Realistic Example

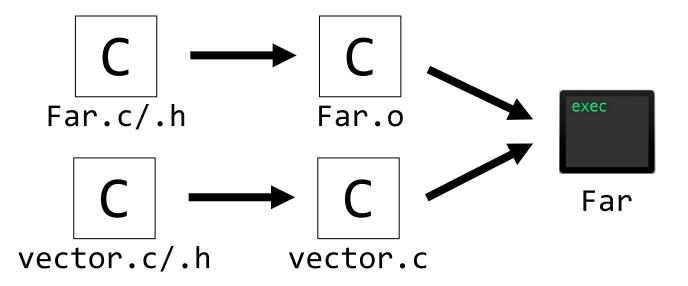

File Archiver

- Target file: Far (an executable)
- Source files: Far.c Far.h vector.c vector.h

Example

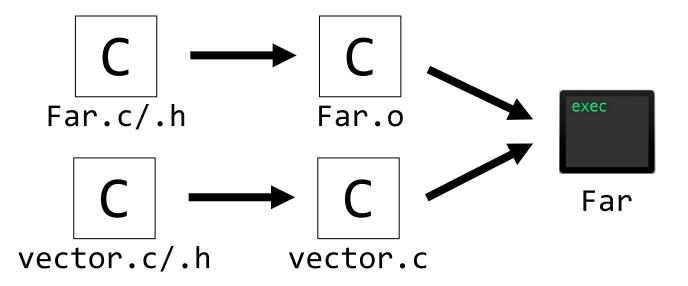

- Target: Far
- Ingredients: Far.o, vector.o
- Recipe: gcc -o Far Far.o vector.o

Example

- Target: Far
- Ingredients: Far.o, vector.o
- Recipe: gcc -o Far Far.o vector.o

Makefile Demo

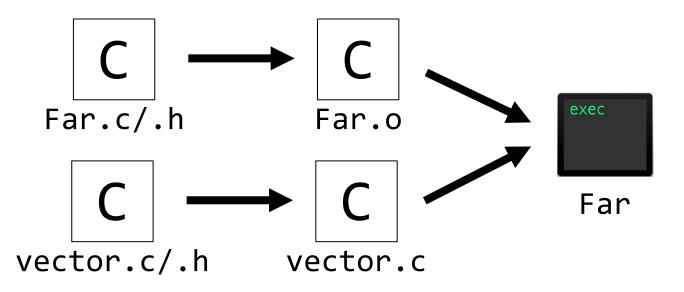

Example

- Target: Far
- Ingredients: Far.o, vector.o
- Recipe: gcc -o Far Far.o vector.o

Makefile Demo

```
CC=gcc
CFLAGS=-g -std=c99 -pedantic -Wall
all: Far

Far: Far.o vector.o
    ${CC} ${CFLAGS} $^ -o $@
Far.o: Far.c Far.h vector.h
    ${CC} ${CFLAGS} -c Far.c
vector.o: vector.c vector.h
    ${CC} ${CFLAGS} -c vector.c
clean:
    ${RM} Far.o vector.o Far
```

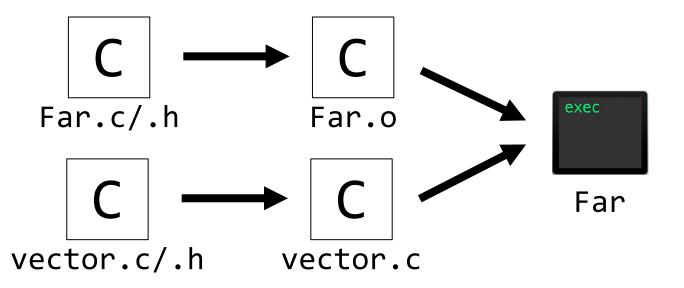

Example

- Target: Far
- Ingredients: Far.o, vector.o
- Recipe: gcc -o Far Far.o vector.o

Good Test Problem!

Suppose I update Far.c, Then call make Far.

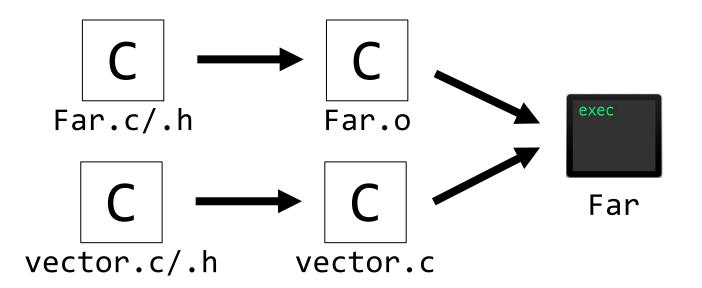

Example

- Target: Far
- Ingredients: Far.o, vector.o
- Recipe: gcc -o Far Far.o vector.o

Good Test Problem!

Suppose I update Far.c, Then call make Far.

Which commands does Make run?

Example

- Target: Far
- Ingredients: Far.o, vector.o
- Recipe: gcc -o Far Far.o vector.o

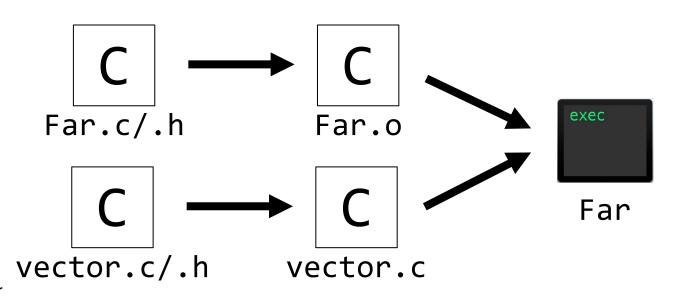

Good Test Problem!

Suppose I update Far.c, Then call make Far.

Which commands does Make run?

Answer:

gcc -g -std=c99 -pedantic -Wall -c Far.c gcc -g -std=c99 -pedantic -Wall Far.o vector.o -o Far

Takeaways

Takeaways from File Archiver Example

- Recursive rules
- Bigger projects practically need Make (or another build system)
- Makefile variables (e.g., CC and CFLAGS)
- Target need not be a file! (e.g., clean)

Generic Makefile

Reusable Makefile

- Any simple project
- Main program and its header
- Can be easily extended to include libraries
- Feel free to copy-paste

Generic Makefile

```
# A simple makefile for building a program composed of C source files.
# Refer to CS107 guide to Make for background info on makefiles
PROGRAMS = hello
all:: $(PROGRAMS)
CC = gcc
FLAGS = -Wl -vervose -g3 -00 -std=gnu99 -Wall $$warnflags
export warnflags = -Wfloat-equal -Wtype-limits -Wpointer-arith -Wshadow -Winit-self -fno-diagnostics-show-option
LDFLAGS =
LDLIBS =
$(PROGRAMS): %:%.c
        $(CC) $(CFLAGS) $(LDFLAGS) $^ $(LDLIBS) -o $@
clean::
        rm -f $(PROGRAMS) *.o
.PHONY: clean all
```

Make Takeaways

In The Wild

- Will see very complex makefiles Don't be intimidated
- Will see other build systems (e.g., CMake) Same idea as Make
- Will see Make for other languages Same source -> executable mapping
