

Learning Goals

- Understand how we can optimize our code to improve efficiency and speed
- Learn about the optimizations GCC can perform

Plan for Today

- Writing cache-friendly code
- Optimization

Disclaimer: Slides for this lecture were borrowed from

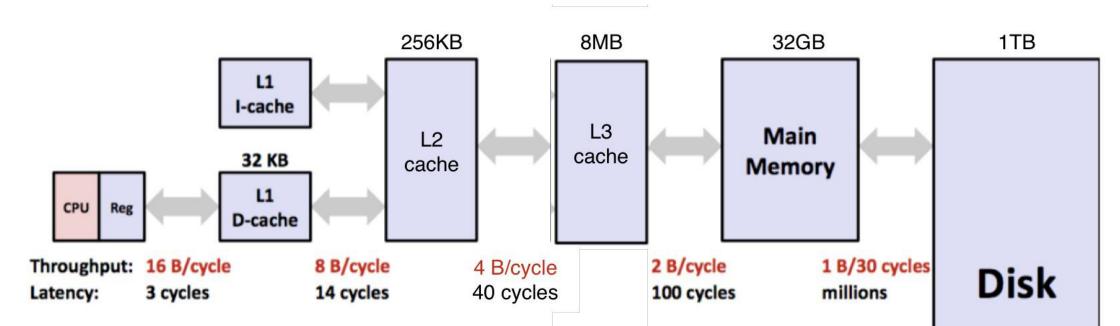

- —Nick Troccoli's Stanford CS107 class
- —Ashley Taylor's Stanford CS106B class

Plan for Today

- Writing cache-friendly code
- Optimization

Caching

- Processor speed is not the only bottleneck in program performance memory access is perhaps even more of a bottleneck!
- Memory exists in levels and goes from *really fast* (registers) to *really slow* (disk).
- As data is more frequently used, it ends up in faster and faster memory.

Caching

All caching depends on locality.

Temporal locality

- Repeat access to the same data tends to be co-located in TIME
- Intuitively: things I have used recently, I am likely to use again soon

Spatial locality

- Related data tends to be co-located in SPACE
- Intuitively: data that is near a used item is more likely to also be accessed

Recap: Memory Mountain Test Function

```
long data[MAXELEMS]; /* Global array to traverse */
/* test - Iterate over first "elems" elements of
          array "data" with stride of "stride", using
*
          using 4x4 loop unrolling.
int test(int elems, int stride) {
    long i, sx2=stride*2, sx3=stride*3, sx4=stride*4;
    long acc0 = 0, acc1 = 0, acc2 = 0, acc3 = 0;
    long length = elems, limit = length - sx4;
    /* Combine 4 elements at a time */
    for (i = 0; i < limit; i += sx4) {
        acc0 = acc0 + data[i]:
        acc1 = acc1 + data[i+stride];
        acc2 = acc2 + data[i+sx2]:
        acc3 = acc3 + data[i+sx3];
    /* Finish any remaining elements */
    for (; i < length; i++) {</pre>
       acc0 = acc0 + data[i]:
    return ((acc0 + acc1) + (acc2 + acc3));
```

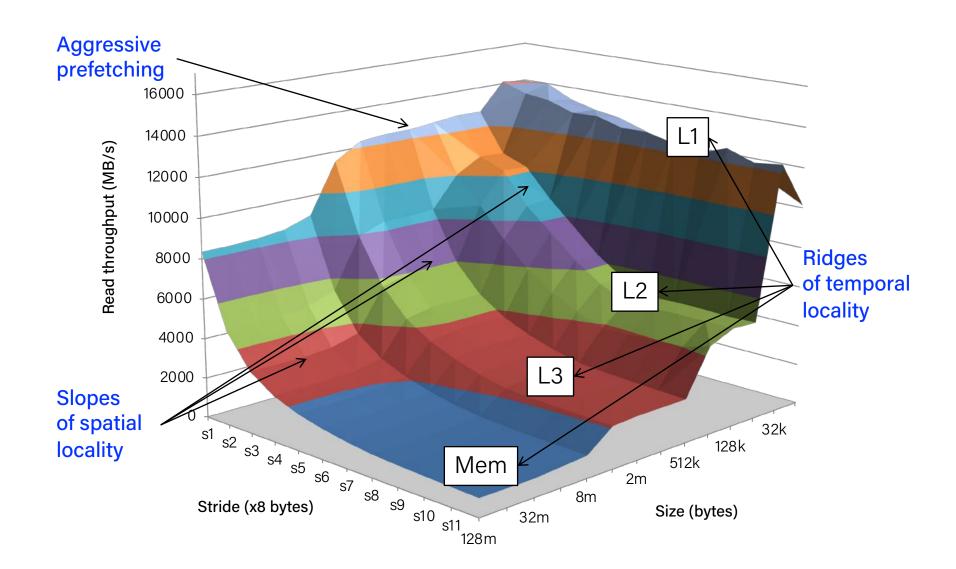

Call test() with many combinations of elems and stride.

For each elems and stride:

- 1. Call test() once to warm up the caches.
- 2. Call test() again and
 measure the read
 throughput(MB/s)

mountain/mountain.c

Recap: The Memory Mountain

Core i7 Haswell 2.1 GHz 32 KB L1 d-cache 256 KB L2 cache 8 MB L3 cache 64 B block size

Writing Cache Friendly Code

- Make the common case go fast
 - Focus on the inner loops of the core functions
- Minimize the misses in the inner loops
 - Repeated references to variables are good (temporal locality)
 - Stride-1 reference patterns are good (spatial locality)

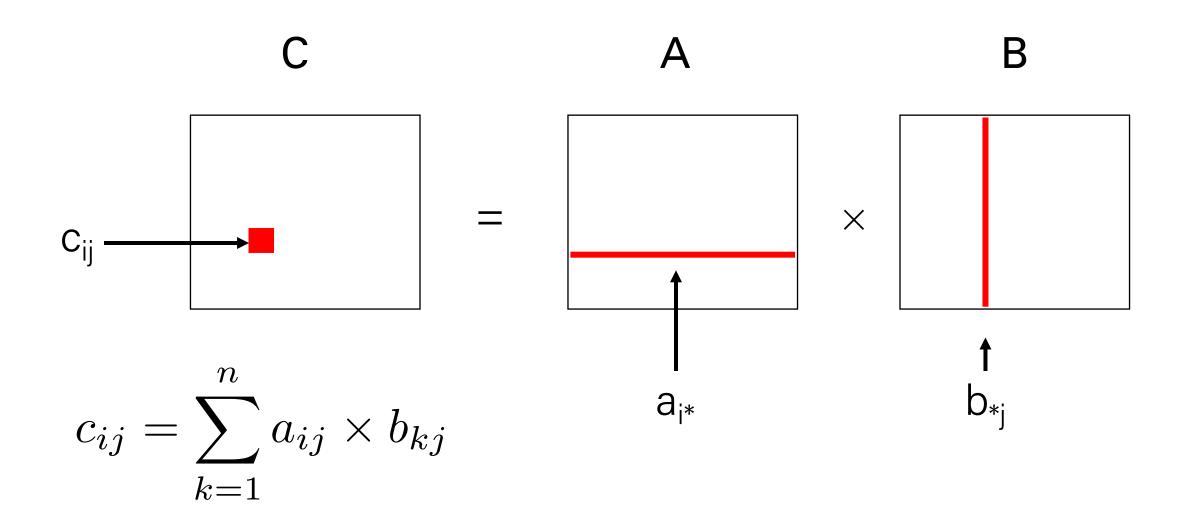

Key idea: Our qualitative notion of locality is quantified through our understanding of cache memories

Lecture Plan

- Writing cache-friendly code
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality
- Optimization

Example: Matrix Multiplication

Matrix Multiplication Example

Matrix Multiplication Example

- Description:
 - Multiply N x N matrices
 - Matrix elements are doubles (8 bytes)
 - O(N³) total operations
 - N reads per source element
 - N values summed per destination
 - but may be able to hold in register

```
/* ijk */
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
    for (k=0; k<n; k++)
       sum += a[i][k] * b[k][j];
    c[i][j] = sum;
  }
}</pre>
```

matmult/mm.c

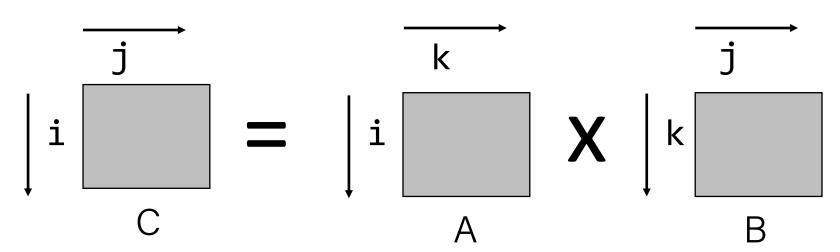

Miss Rate Analysis for Matrix Multiply

Assume

- Block size = 32B (big enough for four doubles)
- Matrix dimension (N) is very large
 - Approximate 1/N as 0.0
- Cache is not even big enough to hold multiple rows

Analysis Method:

Look at access pattern of inner loop

Layout of C Arrays in Memory (review)

- C arrays allocated in row-major order
 - each row in contiguous memory locations
- Stepping through columns in one row:

```
for (i = 0; i < N; i++)
sum += a[0][i];
```

- -accesses successive elements
- -if block size (B) > sizeof(aij) bytes, exploit spatial locality miss rate = sizeof(aij) / B

Stepping through rows in one column:

```
for (i = 0; i < n; i++)
sum += a[i][0];
```

- -accesses distant elements
- -no spatial locality! miss rate = 1 (i.e. 100%)

Matrix Multiplication (ijk)

```
/* ijk */
                                            Inner loop:
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
                                                 (i,*)
                                                      В
    for (k=0; k<n; k++)
      sum += a[i][k] * b[k][j];
    c[i][j] = sum;
                                           Row-wise Column-
                                                            Fixed
                                                   wise
                                 matmult/mm.c
```

Misses per inner loop iteration:

<u>A</u> <u>B</u> <u>C</u> 0.25 1.0 0.0

Matrix Multiplication (jik)

```
/* jik */
                                            Inner loop:
for (j=0; j<n; j++) {
  for (i=0; i<n; i++) {
                                                             (i,j)
    sum = 0.0;
    for (k=0; k<n; k++)
      sum += a[i][k] * b[k][j];
    c[i][j] = sum;
                                            Row-wise Column-
                                                             Fixed
                                                     wise
                                 matmult/mm.c
```

Misses per inner loop iteration:

<u>A</u>	<u>B</u>	<u>C</u>
0.25	1.0	0.0

Matrix Multiplication (kij)

0.25

0.0

0.25

```
/* kij */
                                               Inner loop:
for (k=0; k<n; k++) {
  for (i=0; i<n; i++) {
                                                           (k,*)
                                              (i,k)
                                                                    (i,*)
    r = a[i][k];
    for (j=0; j<n; j++)
       c[i][j] += r * b[k][j];
                                                     Row-wise Row-wise
                                              Fixed
                                   matmult/mm.c
Misses per inner loop iteration:

Summary of Matrix Multiplication

```
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
  for (k=0; k<n; k++)
    sum += a[i][k] * b[k][j];
  c[i][j] = sum;
}</pre>
```

```
for (k=0; k<n; k++) {
  for (i=0; i<n; i++) {
    r = a[i][k];
  for (j=0; j<n; j++)
    c[i][j] += r * b[k][j];
}</pre>
```

```
for (j=0; j<n; j++) {
  for (k=0; k<n; k++) {
    r = b[k][j];
    for (i=0; i<n; i++)
    c[i][j] += a[i][k] * r;
}
</pre>
```

Core i7 Matrix Multiply Performance

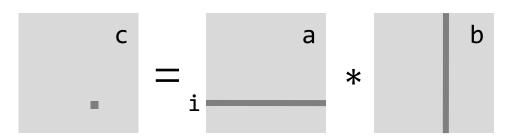

Lecture Plan

- Writing cache-friendly code
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality
- Optimization

Example: Matrix Multiplication

```
c = (double *) calloc(sizeof(double), n*n);

/* Multiply n x n matrices a and b */
void mmm(double *a, double *b, double *c, int n) {
   int i, j, k;
   for (i = 0; i < n; i++)
        for (j = 0; j < n; j++)
        for (k = 0; k < n; k++)
        c[i*n + j] += a[i*n + k] * b[k*n + j];
}</pre>
```

Cache Miss Analysis

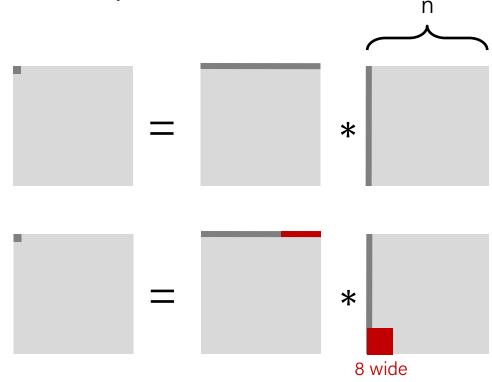

Assume

- Matrix elements are doubles
- Cache block = 8 doubles
- Cache size C << n (much smaller than n)</p>

First iteration:

- n/8 + n = 9n/8 misses

Afterwards in cache: (schematic)

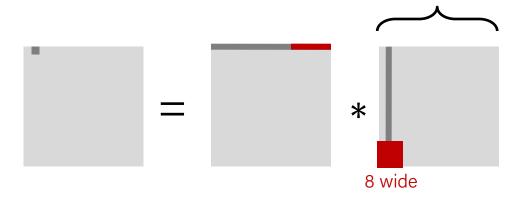

Cache Miss Analysis

Assume

- Matrix elements are doubles
- Cache block = 8 doubles
- Cache size C << n (much smaller than n)</p>

Second iteration:

- Again: n/8 + n = 9n/8 misses

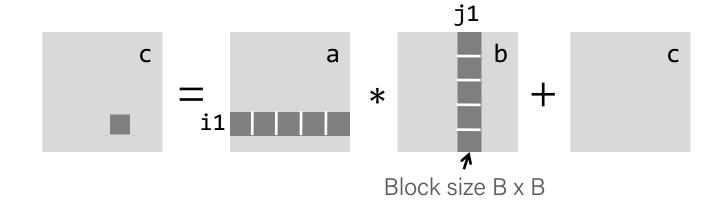

Total misses:

 $-9n/8 * n^2 = (9/8) * n^3$

Blocked Matrix Multiplication

matmult/bmm.c

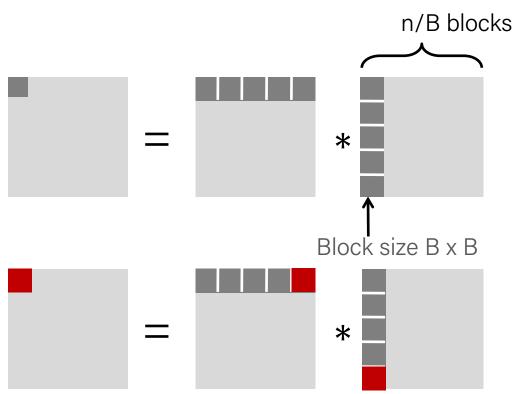

Cache Miss Analysis

Assume

- Cache block = 8 doubles
- Cache size C << n (much smaller than n)
- Three blocks fit into cache: 3B² < C

First (block) iteration:

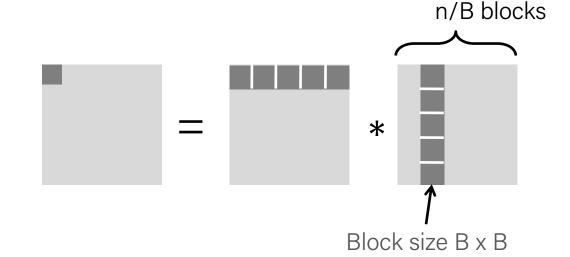

- B²/8 misses for each block
- -2n/B * B²/8 = nB/4 (omitting matrix c)
- Afterwards in cache (schematic)

Cache Miss Analysis

- Assume:
 - Cache block = 8 doubles
 - Cache size C << n (much smaller than n)
 - Three blocks fit into cache: 3B² < C

- Second (block) iteration:
 - Same as first iteration
 - -2n/B * B²/8 = nB/4

- Total misses:
 - $nB/4 * (n/B)^2 = n^3/(4B)$

Blocking Summary

- **No blocking:** (9/8) * n³
- **Blocking:** 1/(4B) * n³

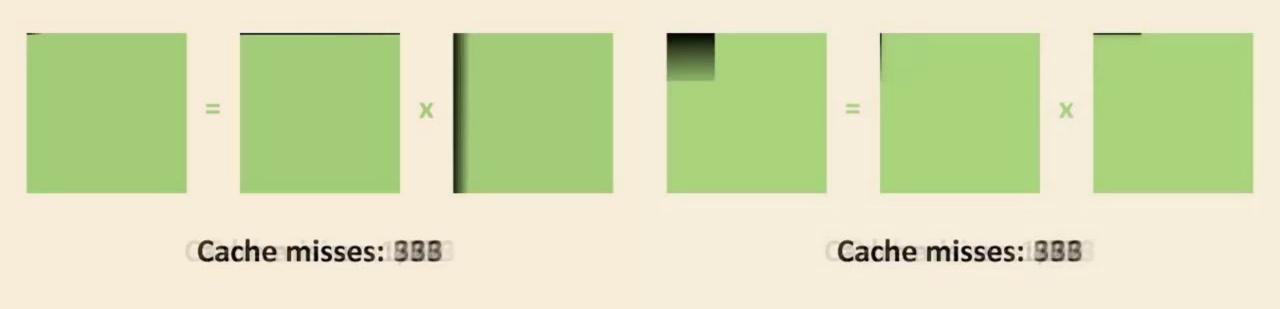

Suggest largest possible block size B, but limit 3B² < C!

- Reason for dramatic difference:
 - Matrix multiplication has inherent temporal locality:
 - Input data: 3n², computation 2n³
 - Every array elements used O(n) times!
 - But program has to be written properly

Naïve vs. Blocked Matrix Multiplication

Naïve Multiplication

Blocked Multiplication

 \approx 1,020,000 cache misses

≈ 90,000 cache misses

Recap

- Cache memories can have significant performance impact
- You can write your programs to exploit this!
 - Focus on the inner loops, where bulk of computations and memory accesses occur.
 - Try to maximize spatial locality by reading data objects with sequentially with stride 1.
 - Try to maximize temporal locality by using a data object as often as possible once it's read from memory.

Lecture Plan

- Writing cache-friendly codes
- Optimization
 - What is optimization?
 - GCC Optimization
 - Limitations of GCC Optimization
 - Caching revisited

Optimization

- Optimization is the task of making your program faster or more efficient with space or time. You already know explorations of efficiency with Big-O notation!
- Targeted, intentional optimizations to alleviate bottlenecks can result in big gains. But it's important to only work to optimize where necessary.

Optimization

Most of what you need to do with optimization can be summarized by:

- If doing something seldom and only on small inputs, do whatever is simplest to code, understand, and debug
- 2) If doing things a lot, or on big inputs, make the primary algorithm's Big-O cost reasonable
- 3) Let gcc do its magic from there
- 4) Optimize explicitly as a last resort

- Today, we'll be comparing two levels of optimization in the gcc compiler:
 - gcc -00 // mostly just literal translation of C
 - gcc -02 // enable nearly all reasonable optimizations
 - (we use -0g, like -00 but with less needless use of the stack)
- There are other custom and more aggressive levels of optimization, e.g.:

```
    - -03 //more aggressive than -02, trade size for speed
    - -0s //optimize for size
    - -Ofast //disregard standards compliance (!!)
```

- Exhaustive list of gcc optimization-related flags:
 - https://gcc.gnu.org/onlinedocs/gcc/Optimize-Options.html

Example: Matrix Multiplication

Here's a standard matrix multiply, a triply-nested for loop:

```
void mmm(double a[][DIM], double b[][DIM], double c[][DIM], int n) {
    for (int i = 0; i < n; i++) {
        for (int j = 0; j < n; j++) {
            for (int k = 0; k < n; k++) {
                c[i][j] += a[i][k] * b[k][j];
            }
        }
    }
}</pre>
```

```
./mult // -00 (no optimization)
matrix multiply 25^2: cycles 0.43M
matrix multiply 50^2: cycles 3.02M
matrix multiply 100^2: cycles 24.82M
```

```
./mult_opt // -02 (with optimization)
matrix multiply 25^2: cycles 0.13M (opt)
matrix multiply 50^2: cycles 0.66M (opt)
matrix multiply 100^2: cycles 5.55M (opt)
```

- Constant Folding
- Common Sub-expression Elimination
- Dead Code
- Strength Reduction
- Code Motion
- Tail Recursion
- Loop Unrolling

Optimizations may target one or more of:

- Static instruction count
- Dynamic instruction count
- Cycle count / execution time

- Constant Folding
- Common Sub-expression Elimination
- Dead Code
- Strength Reduction
- Code Motion
- Tail Recursion
- Loop Unrolling

Constant Folding

Constant Folding pre-calculates constants at compile-time where possible.

int seconds = 60 * 60 * 24 * n_days;

What is the consequence of this for you as a programmer? What should you do differently or the same knowing that compilers can do this for you?

Constant Folding

```
int fold(int param) {
    char arr[5];
    int a = 0x107;
    int b = a * sizeof(arr);
    int c = sqrt(2.0);
    return a * param + (a + 0x15 / c + strlen("Hello") * b - 0x37) / 4;
}
```

Constant Folding: Before (-00)

```
00000000000400626 <fold>:
  400626:
                                                     %rbp
                  55
                                              push
                  53
  400627:
                                              push
                                                     %rbx
                  48 83 ec 08
                                                     $0x8,%rsp
  400628:
                                              sub
                  89 fd
  40062c:

Common Sub-Expression Elimination

Common Sub-Expression Elimination prevents the recalculation of the same thing many times by doing it once and saving the result.

```
int a = (param2 + 0x201);
int b = param1 * (param2 + 0x201) + a;
return a * (param2 + 0x201) + b * (param2 + 0x201);
```

Common Sub-Expression Elimination

Common Sub-Expression Elimination prevents the recalculation of the same thing many times by doing it once and saving the result.

```
This optimization is
 int a = (param2 + 0x201);
                                                 done even at -00!
int b = param1 * (param2 + 0x201) + a;
return a * (param2 + 0x201) + b * (param2 + 0x201);

Dead Code

Dead code elimination removes code that doesn't serve a purpose:

```
if (param1 < param2 && param1 > param2) {
    printf("This test can never be true!\n");
// Empty for loop
for (int i = 0; i < 1000; i++);
// If/else that does the same operation in both cases
if (param1 == param2) {
    param1++;
} else {
    param1++;
// If/else that more trickily does the same operation in both cases
if (param1 == 0) {
    return 0;
} else {
    return param1;
```

Dead Code: Before (-O0)

```
00000000004004d6 <dead code>:
            b8 00 00 00 00

```

Dead Code: After (-O2)

- Constant Folding
- Common Sub-expression Elimination
- Dead Code
- Strength Reduction
- Code Motion
- Tail Recursion
- Loop Unrolling

Strength Reduction

Strength reduction changes divide to multiply, multiply to add/shift, and mod to AND to avoid using instructions that cost many cycles (multiply and divide).

```
int a = param2 * 32;
int b = a * 7;
int c = b / 3;
int d = param2 \% 2;
for (int i = 0; i <= param2; i++) {
    c += param1[i] + 0x107 * i;
return c + d;
```

Strength Reduction: After (-O3)

```
unsigned udiv19(unsigned arg) {
return arg / 19;
}
```

```
udiv19(unsigned int):
    mov eax, edi
    mov edx, 2938661835
    imul rax, rdx
    shr rax, 32
    sub edi, eax
    shr edi
    add eax, edi
    shr eax, 4
    ret
```

https://godbolt.org/z/Wq8ra3

What really happens here?

$$a \cdot \frac{1}{19} \approx \frac{a \cdot \frac{2938661835}{2^{32}} + \frac{a - a \cdot \frac{2938661835}{2^{32}}}{2^{4}}}{2^{4}}$$

$$a \cdot \frac{1}{19} \approx \left(a \cdot 2938661835 \cdot 2^{-32} + \left(a - a \cdot 2938661835 \cdot 2^{-32}\right) \cdot 2^{-1}\right) \cdot 2^{-4}$$

$$a \cdot \frac{1}{19} \approx a \cdot \frac{7233629131}{137438953472}$$

- Constant Folding
- Common Sub-expression Elimination
- Dead Code
- Strength Reduction
- Code Motion
- Tail Recursion
- Loop Unrolling

Code Motion

Code motion moves code outside of a loop if possible.

```
for (int i = 0; i < n; i++) {
   sum += arr[i] + foo * (bar + 3);
}</pre>
```

Common subexpression elimination deals with expressions that appear multiple times in the code. Here, the expression appears once, but is calculated each loop iteration.

- Constant Folding
- Common Sub-expression Elimination
- Dead Code
- Strength Reduction
- Code Motion
- Tail Recursion
- Loop Unrolling

Tail Recursion

Tail recursion is an example of where GCC can identify recursive patterns that can be more efficiently implemented iteratively.

```
long factorial(int n) {
   if (n <= 1) {
      return 1;
   }
   else return n * factorial(n - 1);
}</pre>
```

Tail Recursion

Tail recursion: When a recursive call is made as the <u>final</u> action of a recursive function.

```
long factorial(int n) {
   if (n <= 1) {
      return 1;
   }
   else return n * factorial(n - 1);
}</pre>
```

Tail-recursive factorial

```
// returns n!, or 1 * 2 * 3 * 4 * ... * n.
long factorial(int n, long accum = 1) {
   if (n <= 1) {
      return accum;
   }
   else return factorial(n - 1, accum * n);
}</pre>
```

 Tail recursive solutions often end up passing partial computations as parameters that would otherwise be computed after the recursive call

Non-recursive factorial

```
// returns n!, or 1 * 2 * 3 * 4 * ... * n.
long factorial(int n) {
   long accum = 1;
   for (int i = 1; i <= n; i++) {
       accum *= i;
   }
   return accum;
}</pre>
```

- Sometimes looking at the non-recursive version of a function can help you find the tail recursive solution
 - Often looks more like the non-recursive version, with a variable or parameter keeping track of partial computations
 - Loop is replaced by a recursive call

- Constant Folding
- Common Sub-expression Elimination
- Dead Code
- Strength Reduction
- Code Motion
- Tail Recursion
- Loop Unrolling

Loop Unrolling

Loop Unrolling: Do **n** loop iterations' worth of work per actual loop iteration, so we save ourselves from doing the loop overhead (test and jump) every time, and instead incur overhead only every n-th time.

```
for (int i = 0; i <= n - 4; i += 4) {
    sum += arr[i];
    sum += arr[i + 1];
    sum += arr[i + 2];
    sum += arr[i + 3];
} // after the loop handle any leftovers</pre>
```

Limitations of GCC Optimization

GCC can't optimize everything! You ultimately may know more than GCC does.

```
int char_sum(char *s) {
    int sum = 0;
    for (size_t i = 0; i < strlen(s); i++) {
        sum += s[i];
    }
    return sum;
}</pre>
```

What is the bottleneck? **strlen called for every character**What can GCC do? **code motion - pull strlen out of loop**

Limitations of GCC Optimization

GCC can't optimize everything! You ultimately may know more than GCC does.

```
void lower1(char *s) {
    for (size_t i = 0; i < strlen(s); i++) {
        if (s[i] >= 'A' && s[i] <= 'Z') {
            s[i] -= ('A' - 'a');
        }
    }
}</pre>
```

What is the bottleneck? What can GCC do?

strlen called for every character nothing! s is changing, so GCC doesn't know if length is constant across iterations. But we know its length doesn't change.

Optimizing Your Code

 - Optimize using –02
 - And more...

Compiler Optimizations

Why not always just compile with -02?

- Difficult to debug optimized executables only optimize when complete
- Optimizations may not always improve your program. The compiler does its best, but may not work, or slow things down, etc. Experiment to see what works best!

Why should we bother saving repeated calculations in variables if the compiler has common subexpression elimination?

• The compiler may not always be able to optimize every instance. Plus, it can help reduce redundancy!
